

An Elementary Derivation of the Navier-Stokes Equation and the Sound Wave Equation

Daniel D. Sega

April 1, 2025

Abstract

The Navier-Stokes equation, which is the central equation of fluid dynamics, is seldom though at the undergraduate level, let alone in an introductory physics class. As a consequence, actual fluid dynamics at the professional level looks nothing like the introductory physics fluid dynamics, and the students do not get a taste of what the discipline is all about and whether they would like to pursue it. This manuscript is an attempt to derive the Navier-Stokes equation, and the wave equation for sound waves, at the level of a Calculus base introductory physics class.

The way to mathematically analyze a fluid is by considering a differential volume-element, or a *parcel* (see Fig. 1), and considering the forces acting on this parcel. First, I will recount how this method gives us the pressure equation for a liquid at equilibrium in a gravitational field (Fluid Statics); later, I will derive the Navier-Stokes equation with similar considerations.

1 Fluid Statics

Consider Figure 1. This represents a differential fluid element, or parcel, in the form of a cube with sides dx , dy , and dz . Such that the volume is given by $dV = dxdydz$. In a static situation, this cube does not move. This means that the pressure—which is a product of the particles in the fluid colliding with the walls on the cube due to their random (thermal) motion—cancels out the effects of gravity. Gravity’s nature is to bring the fluid parcel downwards (towards the center of the Earth), so the net force due to pressure must be upward. We hence have, from Newton’s second law:

$$F_{y_{net}} = -m_{\text{parcel}}g + \Delta_y P * dxdy = 0 \quad (1)$$

Figure 1: A (zoomed-in) differential volume element (or parcel) on a static fluid. For the fluid to be in static equilibrium, an upward force, produced by the pressure of the surrounding fluid on the parcel, must balance the weight of the parcel

where g is the gravitational acceleration, P is the pressure, and Δ_y represents the change in pressure between the top and bottom faces of the cube. In a fluid, pressure exerts a net force on a fluid parcel when there is a *pressure difference* between opposite faces. The change in pressure along a length dz (from one face to the other) is given by the derivative of the pressure in the z -direction, times the length dz . To see this, consider that the pressure in the bottom face is P_0 , then by a first-order Taylor expansion, the pressure in the top face will be $P_0 + \frac{dP}{dz}dz$. Here, we are assuming the pressure to vary linearly within the cube, which is a good approximation given that the cube is infinitesimal. $\Delta_y P$ is then given by the difference in these two pressures:

$$\Delta_y P = P_{\text{bottom}} - P_{\text{top}} = P_0 - (P_0 + \frac{dP}{dz}dz) = -\frac{dP}{dz}dz$$

Eqn. 1 then becomes:

$$F_{y_{net}} = -m_{\text{parcel}}g - \frac{dP}{dz}dzdxdy = 0 \quad (2)$$

Dividing by the differential volume dV and recognizing that $\frac{m_{\text{parcel}}}{dV} = \rho$ (where ρ is the density of the fluid) we find that

$$\frac{dP}{dz} = -\rho g \quad (3)$$

If we consider an ambient pressure P_{atm} over a liquid, we might want to know how the pressure will change when descending a depth $-d$ into the fluid (the negative is because the displacement is downwards). Integrating this equation we find that

$$\int_{P_{\text{atm}}}^P P' = - \int_0^{-d} \rho g dz$$

$$P = P_{\text{atm}} + \rho g d \quad (4)$$

This is how the pressure increases as we dive further into the sea or a pool of water.

2 Fluid Dynamics: The Navier-Stokes Equation

This is similar to what we did when doing fluid statics: we derived the pressure-depth relationship by considering a fluid parcel in equilibrium in a fluid container. Now the parcel can have a net velocity and acceleration, so the analysis gets more involved, but we still use the same methodology as in fluid statics.

Consider the volume element in Fig. 2. What are the forces in the volume-element? These will be due to the neighboring particles (neglecting gravity for now). There are two types of forces neighboring particles will exert on the fluid parcel. One is collisional. The particles will collide with the faces of the cube and exert a pressure on the cube, pushing in on the walls of the cube. Pressure captures the forces due to the collisions given the random (thermal) motions of the fluid. Like the case of electrostatic, the net influence of pressure depends on how its difference between the faces of the cube. While in the electrostatic case there was only a pressure difference in the vertical z -axis (because this difference was balancing gravity's influence), now there can be a pressure difference in the x , and y -axis as well. Hence:

$$F_{Px} = \Delta_x P = \left(-\frac{\delta P}{\delta x} dx\right) dy dz \quad (5)$$

$$F_{Py} = \Delta_y P = \left(-\frac{\delta P}{\delta y} dy\right) dx dz \quad (6)$$

Figure 2: A differential volume-element in a flow. Each face of the cube is labeled with a number. The face normal to the x-axis is 1, to the y-axis is 2, and to the z-axis is 3.

$$F_{Pz} = \Delta_z P = \left(-\frac{\delta P}{\delta z} dz\right) dx dy \quad (7)$$

where we have multiplied by the area of each face ($dydz$, $dx dz$, and $dx dy$, respectively) to obtain the net force on those faces (recall that force in pressure times the area). The negative sign comes about because, when the pressure increases in one direction, the net force will be opposite to this direction (as the higher-pressure side will be pushed opposite to this pressure increase).

The second force is attractive and related to drag or *viscosity*. Inter-molecular forces want to stick fluid particles together, so if a fluid molecule passes by another one, this will feel an attractive force towards the passing particle. This effect is called viscous shear.

Consider, for instance, face 2 of the cube. There are four possible interactions with the sur-

rounding particles that will produce a force on this wall, which are shown in Fig. 3. The cyan, magenta and green particles are passing by the wall and exerting an attractive inter-molecular force that is represented as a viscous drag. Let's consider the force due to the magenta particle. A net force on the cube due to magenta particles (particle flowing in the +y direction) will only exist if the magenta particles have a different velocity than the face of the parcel. If they are at the same velocity, then no drag will be experienced (the way this inter-molecular attraction works, is that the parcel's fluid particle only wants to follow the particles that pass by them). Hence, the force due to magenta particles in face 2 F_{M2} depends on the change in velocity of the fluid in the y-direction with respect to the velocity of the parcel itself (referred to as $v_y(0)$)

$$F_{M2} = \nu(v_y(0) - \frac{\partial v_y}{\partial y} \frac{dy}{2}) \quad (8)$$

where ν is a constant of proportionality called the viscosity, which is related to the strength of the attractive inter-molecular forces. But even if this different in velocity exists, that is not enough to warrant that the magenta particles will exert a net force on the *cubic parcel*. If the same force F_{M2} is being applied in the opposite face, the parcel will not experience a drag. This is because for a fluid parcel, what matters is a difference between the velocity of the magenta particle in face 2 *versus its opposite face*. If both faces have the same pressure (force per area), the cube will not accelerate. In general, the acceleration of the fluid parcel is dictated by the difference in pressure between two opposite faces of the parcel. Hence, the force due to the magenta particles interacting with face 2 and its opposite is given by:

$$F_{M2} = \nu \Delta P_{My} = \nu \overbrace{\left[\underbrace{\left(v_y(0) + \frac{\partial v_y}{\partial y} \bigg|_0 \frac{dy}{2} \right)}_{\text{parcel's and particle's velocity difference}} - \left(v_y(0) - \nu \frac{\partial v_y}{\partial y} \bigg|_0 \frac{dy}{2} \right) \right]}^{\text{change of this difference between the two parallel faces of the cube}} dx dy \quad (9)$$

where, again, ν is the viscosity coefficient of the fluid (which depends on the strength of this inter-molecular flow) and where the terms $(v_y(0) \pm \nu \frac{\partial v_y}{\partial y} \big|_0 \frac{dy}{2})$ represent the change in velocity between the cube and the magenta particles on both faces of cube. It is the difference between this change (hence, the second derivative) that matters. ν relates the pressure on the faces of the parcel to the shear, so, to obtain the force, we have to multiply by the area of the face $dx dz$ (recall that force is pressure times the area). Simplifying this equation, we get:

$$F_{M2} = \nu \frac{\partial^2 v_y}{\partial y^2} dy dx dz \quad (10)$$

Figure 3: The four types of interaction that neighboring fluid particles can have on face 2 (or any other face) of the fluid parcel. The Cyan, magenta, and green particles exert viscous intermolecular forces that, given that this interaction is not the exact same on the opposite face, will cause a net acceleration in their direction of motion. Meanwhile, the blue force collides with face 2 exerting a pressure

Now, consider the forces exerted by the green (cyan) particle on face 2. The particle flows upwards, so the viscous (attractive intermolecular force) will be upwards. But this force will only exist if there is a difference in velocity between face 2 and the green particle, and if this difference itself changes between face 2 and its opposite face. So we are left with the force:

$$F_{G2} = \nu \overbrace{\left[\left(v_z(0) + \frac{\partial v_z}{\partial y} \bigg|_0 \frac{dy}{2} \right) - \left(v_z(0) - \nu \frac{\partial v_z}{\partial y} \bigg|_0 \frac{dy}{2} \right) \right]}^{\text{change of this difference between the two parallel faces of the cube}} \quad \text{parcel's and particle velocity difference} \quad dxdz \quad (11)$$

This again simplifies to:

$$F_{G2} = \nu \frac{\partial^2 v_z}{\partial y^2} dy dx dz \quad (12)$$

Unsurprisingly, by the same argument, the net force due to the cyan particles acting on face 2 and its opposite ends up being:

$$F_{C2} = \nu \frac{\partial^2 v_x}{\partial y^2} dy dx dz \quad (13)$$

Note that the direction of the force due to the shear is the same as the direction of motion of the particles. Magenta particles create a force in the y-direction, cyan in the x, and green in the z. While we considered only the forces in face 2, and its opposite, the net force on the cube will be a consequence of adding all the forces on all the faces of the cube. Magenta particles, as they “slide” on faces 1 and 3, will also produce a force in the y. Conversely, for the green and magenta particles. The net force on the y direction will be given by:

$$F_{\text{net}_y} = - \overbrace{\frac{\partial P}{\partial y} dV}^{\text{difference in pressure}} + \overbrace{\nu \left(\frac{\partial^2 v_y}{\partial y^2} dV \right)}^{\text{cyan particles on face 2}} + \overbrace{\frac{\partial^2 v_x}{\partial x^2} dV}^{\text{cyan particles on face 1}} + \overbrace{\frac{\partial^2 v_z}{\partial z^2} dV}^{\text{cyan particles on face 3}} = m_{\text{parcel}} \frac{dv_y}{dt} \quad (14)$$

where we have equated the net force in the y to the net acceleration in the y times the mass of the parcel. Dividing the right-hand side by dV (the fluid parcel volume):

$$\frac{m_{\text{parcel}}}{dV} \frac{dv_y}{dt} = -\frac{\partial P}{\partial y} + \nu \left(\frac{\partial^2 v_y}{\partial y^2} + \frac{\partial^2 v_x}{\partial x^2} + \frac{\partial^2 v_z}{\partial z^2} \right) \quad (15)$$

and recognizing that $\frac{m_{\text{parcel}}}{dV}$ is the density ρ of the fluid, we get the y component of the Navier-Stoke equation.

$$\rho \frac{dv_y}{dt} = -\frac{\partial P}{\partial y} + \nu \left(\frac{\partial^2 v_y}{\partial y^2} + \frac{\partial^2 v_x}{\partial x^2} + \frac{\partial^2 v_z}{\partial z^2} \right) \quad (16)$$

Here we have made the assumption that the density of the fluid ρ is a constant everywhere. This is true for *incompressible* fluids, like water. We will relax this assumption when dealing with air and sound waves, as air is compressible. This equation, however, is a very

powerful and general tool to describe the behaviors of water, which is incompressible, and no matter the velocity, the density is always $\rho_{H^2O} = 1000 \text{ kg/m}^3$.

3 The fictitious force

A final caveat, however, before we write all the components of the Navier-Stokes equation. Care must be taken when considering the acceleration of the fluid parcel $\frac{dv_y}{dt}$. This acceleration is an acceleration with respect to the frame shown in Fig. 4, which is a frame that “rides” with the fluid parcel itself, keeping itself at the center of the parcel always. This means that this frame is not necessarily an inertial frame. In general, when the frame is not inertial, Newton’s second law can be written as:

$$\mathbf{F} - m\mathbf{a}_{\text{frame}} = m\mathbf{a} \quad (17)$$

where $m\mathbf{a}_{\text{frame}}$ is a fictitious force that arises due to the non-inertial effects of the frame. The final step in our derivation will hence be to add to Equation 16 a fictitious force term $m\mathbf{a}_{\text{frame}_y}$, the y-component of this fictitious force. We compute a_{frame_y} by considering that all the frame is doing, to keep itself on top of the fluid particle, is following the flow of the fluid \mathbf{v} . Consider that at a time interval dt , the frame moves a distance ds along the direction of the flow. What is the change of the v_y when moving along this flow a distance ds ? This is given by:

$$a_{\text{frame}_y} dt = \frac{\partial v_y}{\partial s} ds \quad (18)$$

To obtain the rate of this change on a time interval dt , we divide both sides by dt and find that:

$$a_{\text{frame}_y} = \frac{\partial v_y}{\partial s} \frac{ds}{dt}$$

where $\frac{ds}{dt}$ is the speed of the flow $|\mathbf{v}|$ and the derivative $\frac{d}{ds}$ is a derivative in the direction of the velocity flow. Normally derivatives are taken in the x, y or z direction, but one can take a derivative in any direction via the *directional derivative*. This is defined as:

$$\frac{d}{ds} = \left(\frac{\partial}{\partial x} \hat{i} + \frac{\partial}{\partial y} \hat{j} + \frac{\partial}{\partial z} \hat{k} \right) \cdot \frac{\mathbf{v}}{|\mathbf{v}|}$$

where $\frac{\mathbf{v}}{|\mathbf{v}|}$ yields the unit vector in the direction of the flow. Substituting this into the expression $\frac{\partial v_y}{\partial s} \frac{ds}{dt}$ we get

$$\frac{\partial v_y}{\partial s} \frac{ds}{dt} = \left(\frac{\partial v_y}{\partial x} v_x + \frac{\partial v_y}{\partial y} v_y + \frac{\partial v_y}{\partial z} v_z \right) \frac{\frac{ds}{dt}}{\frac{ds}{dt}} \uparrow$$

Figure 4: In a time dt the frame that follows the fluid parcel travels a differential length ds in the direction of the flow. This will create non-inertial effect on the motions described with respect to this frame. These effects are accounted for by adding a fictitious force.

where we have used the fact that $|v| = \frac{ds}{dt}$. So finally, we correct for the fact of a non-inertial frame by subtracting the term

$$\frac{\partial v_y}{\partial x} v_x + \frac{\partial v_y}{\partial y} v_y + \frac{\partial v_y}{\partial z} v_z$$

to the right-hand side of Eqn. 16.

$$\rho \frac{dv_y}{dt} = -\frac{\partial P}{\partial y} + \nu \left(\frac{\partial^2 v_y}{\partial y^2} + \frac{\partial^2 v_x}{\partial x^2} + \frac{\partial^2 v_z}{\partial z^2} \right) - \rho \left[\frac{\partial v_y}{\partial x} v_x + \frac{\partial v_y}{\partial y} v_y + \frac{\partial v_y}{\partial z} v_z \right] \quad (19)$$

Again, this final term, in the square brackets, is a fictitious force (like the centrifugal force) that arises because we considered a non-inertial frame which follows the fluid parcel around

the flow. The x, and z components of the Navier-Stokes equations are similarly written as:

$$\rho \frac{dv_z}{dt} = -\frac{\partial P}{\partial z} + \nu \left(\frac{\partial^2 v_z}{\partial y^2} + \frac{\partial^2 v_z}{\partial x^2} + \frac{\partial^2 v_z}{\partial z^2} \right) - \rho \left[\frac{\partial v_z}{\partial x} v_x + \frac{\partial v_z}{\partial y} v_y + \frac{\partial v_z}{\partial z} v_z \right] \quad (20)$$

$$\rho \frac{dv_x}{dt} = -\frac{\partial P}{\partial x} + \nu \left(\frac{\partial^2 v_x}{\partial y^2} + \frac{\partial^2 v_x}{\partial x^2} + \frac{\partial^2 v_x}{\partial z^2} \right) - \rho \left[\frac{\partial v_x}{\partial x} v_x + \frac{\partial v_x}{\partial y} v_y + \frac{\partial v_x}{\partial z} v_z \right] \quad (21)$$

Now we will simplify this equation by considering a steady-state two-dimensional flow, and finally simplify the equation further by considering a fluid with no viscosity ($\nu = 0$).

4 A steady-state one dimensional flow

In physics, “steady-state” refer to a set of equations that do not change in time. A steady-state of a fluid is similar to the notion of *static equilibrium* in mechanics: the acceleration in all directions is zero. Moreover, when a fluid’s velocity only has component (v_y) and the flow velocity only changes in a direction perpendicular to this flow (the z direction) we have a *one dimensional flow*. Note that this not mean the fluid itself does to extend in three dimensions, rather, it means the fluid only flows in two dimensions. Considering we have such a fluid, the Navier-Stokes equations reduce to:

$$0 = -\frac{\partial P}{\partial z} + \nu \frac{\partial^2 v_z}{\partial z^2} - \rho \left[\frac{\partial v_z}{\partial z} v_z \right] \quad (22)$$

or

$$\rho \left[\frac{\partial v_z}{\partial z} v_z \right] = -\frac{\partial P}{\partial z} + \nu \frac{\partial^2 v_z}{\partial z^2} \quad (23)$$

Note that, while the acceleration with respect to the non-inertial frame may vanish, the frame itself can be accelerated, so the fictitious force term survives. In this class, we will solve simple problems with these equations and with the following equation, which considers a fluid with no viscosity.

5 Inviscid fluids

If the fluid has no appreciable intermolecular forces (like a noble gas), we may consider it to be inviscid; that is, it’s viscosity $\nu = 0$. In this case the viscosity terms vanish and we are left with the equations.

$$\rho \left[\frac{\partial v_z}{\partial y} v_y + \frac{\partial v_z}{\partial z} v_z \right] = -\frac{\partial P}{\partial z} \quad (24)$$

$$\rho \left[\frac{\partial v_y}{\partial y} v_y + \frac{\partial v_y}{\partial z} v_z \right] = - \frac{\partial P}{\partial y} \quad (25)$$

These are called the Euclid equations for a two-dimensional flow. Note, however, that for gasses, in many situations, the incompressibility assumption fails, and we must consider that ρ can change. An example of that lies in the next section.

6 Sound Waves

Thus far, we have only dealt with incompressible fluids. While this works extremely well for liquids, (particularly water). Gases, however, do then to be invicid (no viscosity). What follows is a derivation of the wave equation for a compressible invicid fluid that starts at equilibrium (at rest).

Since the fluid is by requirement initially at rest, our non-inertial term (the fictitious force) vanishes in this case. Parting from Eqn. 22, but changing this to be in the y-axis and setting the viscosity to zero, we get

$$0 = - \frac{\partial P}{\partial y} + \frac{\partial^2 v_y}{\partial y^2} - \rho \left[\frac{\partial v_y}{\partial y} v_y \right] \quad (26)$$

Note, however, that even if there is no average fluid flow, sound waves are not in a steady state: the wave itself means the fluid is sometimes accelerating. Hence, we must replace the 0 in the left-hand side by the acceleration term $\frac{\partial \rho v_y}{\partial t}$ (here we need to leave ρ inside of the time derivative because we are dealing with a compressible fluid).

$$\frac{\partial(\rho v_y)}{\partial t} = - \frac{\partial P}{\partial y} \quad (27)$$

For the next step we must consider two things: one is the conservation of mass constrains the change of ρ (we will see how). The other one is that thermodynamics (the ideal gas law) yields a relation between pressure P and density ρ which we will use.

6.1 The continuity equation (conservation of mass)

The density of a compressible fluid ρ can change in time and in space. For a one dimensional fluid, that means that it depends on the position of the fluid parcel along the y-axis, and the time t elapsed. But density cannot decrease out of thin air, if it decreases at a point y in a time dt then this mass flowed with a velocity v_y through an area A into this a new point $y + dy$. The mass of the volume that flowed is:

$$M_{\text{flowed out}} = \rho A v_y dt$$

By conservation of mass, this equals the change of mass $d\rho$ of the parcel over a time dt . Consider the volume of this parcel to be $dV = A dy$

$$M_{\text{loss}} = -d\rho A dy = -\frac{\partial \rho}{\partial t} dt A dy$$

where the negative sign comes about because the energy in the parcel is decreasing. By conservation of mass, these two expressions must be equal, we get:

$$\frac{\partial \rho}{\partial t} dt A dy = \rho A v_y dt$$

Dividing both sides by dt and dy and noticing that the areas A cancel out, we see that conservation of mass implies that:

$$\frac{\partial \rho}{\partial t} = \frac{\partial(\rho v_y)}{\partial y} = \frac{\partial \rho}{\partial y} v_y + \rho \partial v_y \partial y \quad (28)$$

6.2 Ideal Gases

(TL;DR: In gases, pressure and density are related linearly by a constant c such that $P = c^2 \rho$)

Ideal gases (which we are superficially cover by the end of the class, and it is covered extensively in Chem 1) provide us with a relation between pressure and density, which we need to derive the wave equation from the Navier-Stokes Equation. Normally, the idea gas law is written as

$$PV = NRT$$

where R is Avogadro's number, N in the total number of moles in the gas, and T in the temperature. If we write it instead in terms of the total number of gas *molecules* N_m , we just need to use the Boltzmann constant k_B instead of Avogadro's number.

$$PV = N_m k_B T$$

We can divide both sides by V in order to obtain a relationship between *number density* (number of molecules per unit volume) and pressure

$$P = \frac{N_m}{V} k_B T$$

If we multiply both sides by the mass of the air molecule (which is usually the mass of the N_2 molecule as air on Earth is mostly hydrogen) we find that:

$$PM_{N_2} = \frac{M_{N_2}N_m}{V}k_B T$$

Note that the mass of each molecule multiplied by the total number of molecules N_m is *just the total mass of the gas*. Hence, the fraction is just ρ and we find that:

$$P = \frac{k_B T}{M_{N_2}} \rho$$

where $\frac{k_B T}{M_{N_2}}$ is a constant of the gas (the temperature doesn't change due to the sound wave). To simplify this equation, we write this constant as c^2 , and we finally get:

$$P = c^2 \rho \quad (29)$$

The reason for defining $c = \sqrt{\frac{k_B T}{M_{N_2}}}$ instead of simply $c = \frac{k_B T}{M_{N_2}}$ will become clear in the next (and final) section.

7 Derivation of the wave equation

We are now in position for deriving the wave equation combining Eqns. 27, 28, and 29. First, we need to derive Eqn. 28 with respect to time (remember that ρ is a function of time so it needs to be considered in the derivative as well).

$$\frac{\partial^2 \rho}{\partial t^2} = \overbrace{\frac{\partial^2 \rho}{\partial t \partial y} v_y + \frac{\partial \rho}{\partial y} \frac{\partial v_y}{\partial t} + \frac{\partial \rho}{\partial t} \frac{\partial v_y}{\partial y} + \rho \frac{\partial^2 v_y}{\partial y \partial t}} \quad (30)$$

Now we derive Eqn. 27 with respect to y (we also apply the product rule on the derivative $\frac{\partial \rho v_y}{\partial t} = \frac{\partial \rho}{\partial t} v_y + \rho \frac{\partial v_y}{\partial t}$)

$$\overbrace{\frac{\partial^2 \rho}{\partial t \partial y} v_y + \frac{\partial \rho}{\partial t} \frac{\partial v_y}{\partial y} + \rho \frac{\partial^2 v_y}{\partial y \partial t} + \frac{\partial \rho}{\partial y} \frac{\partial v_y}{\partial t}} = - \frac{\partial^2 P}{\partial y^2} \quad (31)$$

Note that the terms in the overbrace for both equations *are the same*. So we can replace the left-hand side of Eqn. 31 simply with the term $\frac{\partial^2 \rho}{\partial t^2}$:

$$\frac{\partial^2 \rho}{\partial t^2} = - \frac{\partial^2 P}{\partial y^2} \quad (32)$$

Finally, we replace ρ with the pressure P to via de ideal gas law equation above in order to get an equation of only one variable.

$$c^2 \frac{\partial^2 P}{\partial t^2} = - \frac{\partial^2 P}{\partial y^2}$$

or

$$\frac{\partial^2 P}{\partial t^2} + \frac{1}{c^2} \frac{\partial^2 P}{\partial y^2} = 0$$

Two derivatives in time + two derivatives in space equals zero. *This is the wave equation.* It is the same equation we derived for waves on a string. Note that the general form of the wave equation is:

$$\frac{\partial^2 \psi}{\partial t^2} + \frac{1}{v^2} \frac{\partial^2 \psi}{\partial y^2} = 0$$

By comparing these two last equations, we see that $c = v$. That is, the speed of the traveling pressure wave (sound wave) through a gas is given by $c = \sqrt{\frac{k_B T}{M_{N_2}}}$
